ABSTRACT
Manganese doped Cobalt oxide thin films were deposited on steel substrate by sol-gel spin coat method and investigated the impact of doping on electrochemical behaviour. Cyclic Voltammetry technique was used for the electrochemical characterizations of supercapacitor cells fabricated using the Mn doped Co3O4 thin films as their electrodes. The characterization of the doped electrodes showed a notable effect of the Mn concentration on electrochemical properties and consistently found that with increase in Mn concentration performance of supercapacitor goes on improved, accordingly 1%Mn doped electrode exhibited higher specific capacitance 675F/g at 10mV/s scan rate and good cyclic stability compared to other electrodes with different doping concentrations.

Doping, Cyclic Voltammetry, Scan rate, Stability and Supercapacitor.

INTRODUCTION
The Electrochemical supercapacitors (ESs) are ideal for energy storage that undergoes frequent charge and discharge cycles at high current and short duration. These are considered important energy efficiency devices for rapid energy storage and delivery. Among the advantages of ESs are high power density, environmentally friendly, long cycle life, high efficiency, wide range of operating temperatures, environmental friendliness and safety. ESs also serves as a bridging function for the power/energy gap of traditional dielectric capacitors. These characteristics have made ESs very competitive for applications in electric hybrid vehicles, digital communication devices such as...
mobile phones, digital cameras, electrical tools, pulse laser technique, uninterruptible power supplies and storage of the energy generated by solar cells\textsuperscript{1-3}.

Co\textsubscript{3}O\textsubscript{4} thin film and series of Mn incorporated Co\textsubscript{3}O\textsubscript{4} thin films deposited by sol-gel spin coat method and investigated the influence of doping concentrations of Mn in Cobalt such as 0.001\% to 1\% on electrochemical properties. The deposited samples were denoted by different codes such as, S1, S2, S3, S4, S5, S6, S7 and S8 throughout the paper. Where S1=0\%Mn, S2=0.001\%Mn, S3=0.005\%Mn, S4=0.01\%Mn, S5=0.05\%Mn, S6=0.1\%Mn, S7=0.5\%Mn and S8=1\%Mn doping in cobalt. There are many electrochemical techniques for the characterization of supercapacitor exist, in the present work, cyclic voltammetry (CV) is used for the characterization of thin film electrodes. The capacitive behaviour of Co\textsubscript{3}O\textsubscript{4} and Mn doped Co\textsubscript{3}O\textsubscript{4} electrodes have been studied.

**Cyclic Voltammetry Analysis**

Voltammetry is basically referred to as technique with the common characteristics that the potential of the working electrode is controlled and the resulting current flow is measured. The cyclic voltammogram gives us information on the possible redox reactions of the system, including the Faradaic insertion and extraction reaction, electrode processes, the determination of thermodynamics and kinetics of electron transfer at the electrode/electrolyte interface. The technique involves sweeping the electrode potential between two predetermined values at a known sweep rate\textsuperscript{4}.

In the present study, several sweep rates in the range from 10 to 100 mV/s were used to study scan rate effect on performance of electrodes and scan rate of 500 mV/s was used to test the stability of electrodes.

**EFFECT OF SCAN RATE**

The cyclic voltammetry study is carried out with Co\textsubscript{3}O\textsubscript{4} thin film electrode and Mn doped Co\textsubscript{3}O\textsubscript{4} thin film electrode as working electrodes, platinum wire as counter electrode and SCE as a reference electrode in 0.1M KOH electrolyte. Figure No.1 shows the CV curves of Co\textsubscript{3}O\textsubscript{4} (S1) electrode and Mn doped Co\textsubscript{3}O\textsubscript{4} (S2 to S8) electrodes. Scan rate is varied from 10 to 100 mV/s such as 10 mV/s, 20 mV/s, 40 mV/s, 60 mV/s and 100 mV/s in the potential window ranging from -1.3 V to 0.65 V. From the figures, it is verified that potential window as well as current associated with the CV curve increases with increase in scan rate. Which indicates that voltammetric current is directly proportional to the scan rates of CV and this is an good indication of supercapacitive behaviour\textsuperscript{5-7}.

From the CV curves, it is observed that the reduction and oxidation peaks are visible. This indicates that the electrochemical capacitance of the electrodes mainly results from pseudo capacitance. It is also observed that in comparison with doped films, Co\textsubscript{3}O\textsubscript{4} film showed small current and small potential window. In contrast, doped films have high potential window, large current and good reversible redox activity. The calculated values of specific capacitance (SC) with respect to Mn doping concentrations for different scan rates 10 mV to 100 mV/s are plotted in the Figure No.2. All the electrodes exhibited a common trend of decreasing specific capacitance values against an increasing scan rate. It is well known that for very low scan rates, the specific capacitance values are higher because the ions have a much longer time to penetrate and reside in the electrode pores and form electric double layers, which are needed to generate higher capacitance.

As evidenced from Figure No.2, for lower Mn concentrations (electrodes S2 to S6) there is no much change in the values of SC with variable scan rates. It may be due to the fact that at lower content of Mn incorporation, Co species sustain the redox transition. The charge and mass transfer resistance do not decrease (IR drop) suddenly. At higher content of Mn incorporation (electrodes S7 and S8), SC value increase rapidly. Because at higher %Mn incorporation the charge and mass transfer resistance of Mn/Co species decrease. We can also observe as the Mn doping concentration increases specific capacitance increases from 492 to 675 F/g at 10 mV/s scan rate, 451 to 620 F/g at 20 mV/s, 371 to 524 F/g at 40 mV/s, 327 to 465 F/g at 60 mV/s, 287 to 424 F/g at 80 mV/s, and 265 to 383 F/g at 100 mV/s.
This is due to increase in Mn ion concentration which increases the electrical conductivity of the films. Here electrode S8 showed better SC for all scan rates as compared to others. Electrode S8 showed large area under curve and high value of current as evidenced from CV leading to maximum value of SC, it may be due to capacitive favorable phase of Mn: CO$_3$O$_4$ formed at that incorporation leading to optimal Mn incorporation and formation of good porous nature of the sample as reported in our earlier research article. The interconnected crystallites of both Co$_3$O$_4$ and MnO$_2$ may create many micro pores, which help in electrolyte transport and provide large surface area for charge transport reaction for easy ionic intercalation between species leading to the increase in SC value of S8.

**Stability Study**

Retaining of specific capacitance for long cycles at higher scan rate operation condition is essential for practical applicability of a supercapacitor. Figure No.3 shows CV plots of S1, S3, S6 and S8 electrodes in 0.1 M KOH at higher scan rate 500mV/sec for 1$^{\text{st}}$ and 1000$^{\text{th}}$ cycles. Figure No.4 shows the overall stability result, which indicates that S8 electrode behaves reversibly as an excellent supercapacitor material for a large number of potential cycles. The Co$_3$O$_4$ revealed the cyclic stability up to 66% over 1000 cycles. It indicates that the material behaves reversibly as a good capacitor material for a large number of potential cycles. Wang et al have reported the value of cyclic stability for Co$_3$O$_4$ nanowires up to 90% over 500 potential cycles.

CONCLUSION
Characterization by CV methods consistently found that increase in Mn concentration improved the electrochemical properties of the electrodes. The electrode with 1% Mn exhibited better specific capacitance and cyclic stability compared to other doped electrodes. The specific current of the cyclic voltammograms varies linearly with scan rates in the range of 10mV/s to 100mV/s, demonstrating a high power characteristic for all the electrodes. The specific capacitance obtained for S8 electrode is 675 F/g at 10 mV/s scan rate still retaining a considerable specific capacitance of 383F/g at high scan rate of 100mV/s. It showed a high cyclic stability of about 80% over 1000 cycles. In comparison with pure Co3O4 electrode, manganese doped oxide material showed better supercapacitive performance, among which electrode S8 can be considered as a promising candidate for superacpacitor materials.

ACKNOWLEDGEMENT
The authors wish to express their sincere gratitude to Department of Electronics, D. B. F. Dayanand College of Arts and Science, Solapur, Maharashtra, India for providing necessary facilities to carry out this research work.
